Your universe at the best fit: integrated model with axis offset ℓ_0

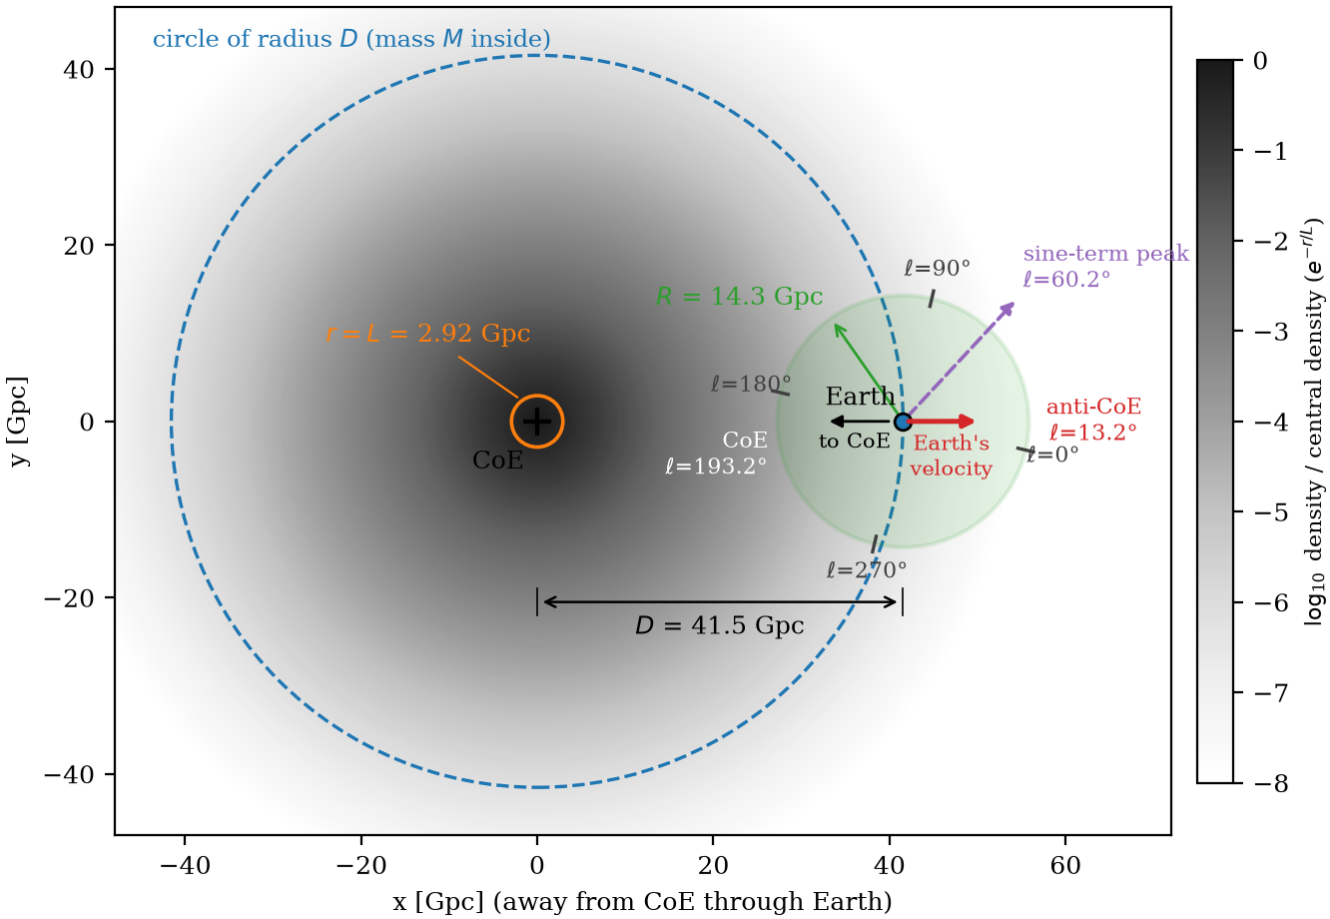

Figure 1: To-scale drawing in the plane of your geometry, in Gpc with equal axes. Grey shading is the $e^{-r/L}$ density on a log scale, the orange circle is $r = L$, and the dashed blue circle of radius D through Earth encloses the mass M. The green disc is the vision shell of radius R centred on Earth. Sky directions around Earth are Galactic longitude with $\theta = \ell - \ell_0$, so $\theta = 0$ (anti-CoE, $\ell = \ell_0$) points away from the CoE along Earth's velocity. The purple arrow marks the peak of the sine term $1 - \mathrm{Amp}\sin(\theta + \varphi)$. The nearest point of the shell lies 9.3 scale lengths from the CoE.

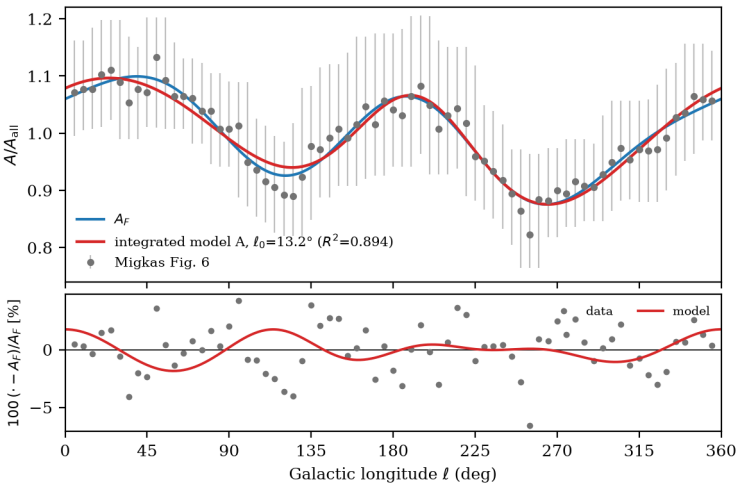

Figure 2: Migkas points with error bars, A_F, and your model A at the best fit. The lower panel shows data and model as percent differences from A_F.

Table 1: Best-fit values in your sheet's cells. This M belongs to the integrated model (real G, integration from $0.01\,t_0$, profile fixed in space) and does not apply to your one-second kick with $1000\,G$. Milky Way mass taken as $10^{12}\,M_\odot$ including dark matter.

Cell	Quantity	Best fit
C23	D/R	2.904
D23	L/D	0.07028
B29	R	4.4127×10^{23} km (14.30 Gpc)
B28	D	1.2816×10^{24} km (41.53 Gpc)
B30	L	9.007×10^{22} km (2.919 Gpc)
B27	M	1.944×10^{54} kg
		$9.77 \times 10^{23}\,M_\odot$
		$\approx 0.98 \times 10^{12}$ Milky Ways
	M/M_{crit} $(H_0 = 70)$	0.0239
BA57	Amp	−0.0509
BA59	φ	0.750 rad
	ℓ_0	13.17°
	k (fixed)	2.18×10^{-18} s^{-1}
	$t_0 = 1/k$	14.5 Gyr
	G (fixed)	6.674×10^{-11} SI
	t_i (fixed)	$0.01\,t_0$
	R^2 vs 71 Migkas points	0.894
	R^2 vs A_F	0.979
